Interlaboratory Comparisons of Static Force Calibrations

1. SCOPE

This report covers phase I of a program of interlaboratory comparisons of static force calibrations developed for the Calibration Coordination group of the Department of Defense. The objective of the program is to allow each participating laboratory to examine the quality of its force calibration capabilities. Phase I includes force measurements up to 20,000 lbf.

2. TEST PROCEDURE

Four force measuring devices were circulated to each of the five participating laboratories. Each was asked to perform calibrations in both tension and compression at, as nearly as possible, ten specified loads over the range of each device. Procedures normally employed by each laboratory were to be used. The devices were divided into two groups, each routed through the laboratories in a different order. All devices were calibrated at the National Bureau of Standards before distribution and again at the termination of the routing. The two groups of devices consisted of the following:

Group A One 2,000-lbf capacity proving ring
One 20,000-lbf capacity proving ring

Group B One 2,000-lbf capacity load cell
One 20,000-lbf capacity load cell
One electronic readout

Both groups of devices were to be calibrated over the same ranges. All laboratories used the same span setting for the load cell system.

3. DATA REDUCTION

The original data for all calibrations were transmitted to the National Bureau of Standards. All data for the proving ring calibrations were corrected to 23 °C. No corrections were applied to the load cell data. Second degree equations, with the load as the independent variable, were fitted to the average load readings from each laboratory using the method of least squares. The initial NBS calibration curves were selected as the base for comparison with the curves fitted to the individual laboratory data. To permit comparisons between devices, all curves were normalized using the initial NBS value at the maximum load (2,000 lbf or 20,000 lbf) as an arbitrary reference. Points on the individual curves corresponding to the nominal calibration loads are expressed as a percentage of the reference base.

4. SUMMARY OF RESULTS

The values from the curves fitted to the primary data, the corresponding normalized values, and the normalized differences from the first-NBS calibration are given in Tables 1 through 8. Standard deviations and curve coefficients for each calibration curve are presented in Table 9. Figures 1 through 6 show comparisons of normalized calibration curves against the initial NBS calibration curves. Two laboratories, A and D, did not calibrate any of the devices in tension.

With the exception of Laboratory C's tension calibration of the 2,000-lbf proving ring, all calibrations agreed to within 0.1 percent of capacity of the reference series of calibrations. There is evidence in Figure 6 that the 2,000-lbf proving ring showed a marked increase in short-term non-linearity during the series of calibrations. This is also suggested by the change in standard deviation in compression shown in Table 9. The small load cell appears to have a uniform change in output increasing to about 0.05 percent at capacity, with respect to the First-NBS calibration. The two 20,000-lbf devices show only insignificant changes.

5. CONCLUSIONS

In general, the intercomparison of data for the 2,000-lbf to 20,000-lbf range agreed to within acceptable limits. The intercomparison of data for the 200-lbf to 2,000-lbf range was inconclusive due to the apparent instability of the test devices being calibrated. Although no serious problem areas were apparent from the data furnished by the various laboratories, there was no basis for evaluation of tension calibration capabilities of the two laboratories that did not supply tension calibration data.

Comparison of the results was complicated by factors such as non-uniformity of test procedures, variations in methods of reporting results, and apparent instability of at least one of the test devices. Information about these factors was obtained that will be useful in planning further tests, but a more comprehensive analysis of the current data did not seem to be justified.

6. RECOMMENDATIONS FOR FUTURE TESTS

If this program is continued, consideration should be given to the following:

1. Greater or smaller load ranges
2. More stable test devices
3. Frequent checks by NBS of instrument stability during laboratory circuit

4. Use of a uniform calibration procedure
5. Full and/or expanded participation of interested laboratories.

Bailey Newark Air Force Station, Newark, Ohio 43055		13. Type of Report & Period Covered Summary 7-15-71 - 12-31-74		
		14. Sponsoring Agency Code		
15. SUPPLEMENTARY NOTES				
16. ABSTRACT (A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here.) This report presents a summary of the first phase of a program developed to intercompare capabilities of DOD calibration laboratories in the parameter of static force measurement. Comparisons of calibrations were made by normalizing the data and plotting second-degree curves.				
17. KEY WORDS (six to twelve entries; alphabetical order; capitalize only the first letter of the first key word unless a proper name; separated by semicolons) Force;force calibration;interlaboratory test;load cell; proving ring;static force
